1. What impact does the depth of a decision tree model have on its complexity and likelihood to underfit or overfit?

1 / 1 point

- ☐ Deep decision trees are simpler models that commonly underfit data, while shallow decision trees are more complex and can result in overfitting
- ☒ Shallow decision trees are simpler models and may underfit data, while very deep decision trees are complex models and may overfit data.
- ☐ The depth of a decision tree does not influence the model's complexity or fit
- ☐ Regardless of depth, all decision tree models are simple and very likely to underfit

✓ Correct

2. When used for a regression task such as predicting demand for a product, how does a decision tree make its predictions?

1 / 1 point

- ☐ We trace the route through the tree for each new observation until we reach a leaf. We then use the majority vote of the class of each point at the leaf as the prediction
- ☐ For each new observation, we look at the training data and find the most similar point, and then use the corresponding target label as the prediction for the new observation
- ☐ For each new observation, we re-train the tree with the data including the observation, and then use the mean target value of the points at the leaf as the prediction.
- ☒ For each new observation, it traces the route through the tree until it reaches a leaf. It then uses the mean target value of the training points at that leaf as the prediction.

✓ Correct

3. Which of the following are correct statements about decision trees (select all that apply)?

1 / 1 point

- ☒ Single decision trees are highly interpretable

✓ Correct

- ☐ Decision trees do not handle non-linear relationships well

- ☒ Decision trees are prone to overfitting on the training data

✓ Correct

- ☒ The fit of a decision tree is highly influenced by the hyperparameters, specifically those which control the tree's depth

✓ Correct

4. What is the goal of using ensemble models rather than individual models?

1 / 1 point

- ☒ Combining multiple models in an ensemble makes the aggregate model less likely to overfit and better at generalizing to new data
- ☐ Ensemble models usually have better prediction performance on the training dataset
- ☐ Ensemble models reduce the computational requirements to train and run the model
- ☐ Ensemble models are more interpretable

✓ Correct

5. When we create an ensemble model, what decisions do we need to make (select all that apply)?

1 / 1 point

- ☒ How we would like to aggregate the predictions of each individual member model to form the prediction for the ensemble (for example, using majority voting, simple average, or weighted average)

✓ Correct

- ☒ How many individual member models we would like to create in the ensemble

✓ Correct

- ☒ Whether we use the same algorithm or different algorithms for each member model

✓ Correct

- ☒ Whether each individual member model is trained on the full dataset or different slices of the data

✓ Correct

6. When we use tree models, why do we often choose to use a Random Forest ensemble model rather than a single decision tree?

1 / 1 point

- ☐ Random Forest models require less computational power to train
- ☐ We can use Random Forest models for both regression and classification, while we can only use decision tree models for classification
- ☒ Using a Random Forest reduces the risk of overfitting relative to a single decision tree
- ☐ Random Forests always generate better predictions than single decision trees on new data

✓ Correct

7. What is a key benefit of tree-based models (decision trees or Random Forests) relative to linear models (linear or logistic regression)?

1 / 1 point

- ☐ Decision tree and Random Forest models are easier to interpret than linear models
- ☒ They can easily model complex, non-linear relationships between the input features and targets with no need for additional feature creation / feature engineering work
- ☐ Tree-based models are less likely to overfit than linear models
- ☐ They always yield better performance than linear models do in generalizing to make predictions on new data

✓ Correct

8. For which of the below applications would we likely use a clustering approach (select all that apply)?

1 / 1 point

- ☐ Modeling and predicting flight delays using historical flight data
- ☒ Segmenting the potential customer base for a new product into groups for the purpose of developing targeted advertising campaigns for each

✓ Correct

- ☒ Organizing food items into groups based on nutritional content

✓ Correct

- ☐ Training a model for use in a car to autonomously parallel park

9. What is the most important (and typically first) decision to make when applying clustering to a problem?

1 / 1 point

- ☒ Determining what basis we will use for measuring similarity / dissimilarity between datapoints (how we will measure which points are similar and which are not)
- ☐ Determining which clustering algorithm we should apply
- ☐ Which metric we will use to evaluate the quality of the clusters formed
- ☐ How we will split our data between training and test sets

✓ Correct

10. Which of the below are true about K-Means clustering (select all that apply)?

1 / 1 point

☒ It is easy to implement and generally converges quickly

 Correct

☒ It is the most popular clustering technique

 Correct

☐ It does not require the user to provide a specific number of clusters to use in the algorithm

☒ It forms linear decision boundaries between the data when separating into clusters

 Correct
